The stress responses are derived based on Eq. (23). Although, we can calculate the stress response at any location of the beam from Eq. (23), for fatigue analysis, we just need concern the point where the max stress response occurs. It is clear that the max stress point is the fixed end of the cantilever beam.

analysis of a cantilever beam. First, the bi-moment and warping stress distributions along the beam length and over the cross section are obtained and, subsequently, the distortional behavior is established based on the theory of a beam on an elastic foundation (BEF) [13]. Finite element analyses (FEAs) using 2D mid-plane element models are

An on-chip test structure was developed by [120, 121] for the fatigue analysis; the experimental arrangements contained an electrostatically driven actuator, sensor, movable mass (responsible of delivering force to the notched beam), and a notched beam. It was demonstrated that large stress reduces the fatigue life cycle.

The mentioned four methods for analysis of fatigue have been implemented in a Matlab code which is described in Chapter 3 of this report, and later shown in the Appendix. The code is then used to study fatigue of a steel I-beam. The studied cross-section of the beam is cyclically loaded with a bending moment and an axial force.

Vibration Fatigue Analysis of a Cantilever Beam Using ...

Vibration fatigue is a mechanical engineering term describing material fatigue, caused by forced vibration of random nature. An excited structure responds according to its natural-dynamics modes, which results in a dynamic stress load in the material points. The process of material fatigue is thus governed largely by the shape of the excitation profile and the response it produces.
