Prolog variables are similar to "unknowns" in algebra: Prolog tries to find values for the variables such that the entire clause can succeed. Once a value has been chosen for a variable, it cannot be altered by subsequent code; however, if the remainder of the clause cannot be satisfied, Prolog may backtrack and try another value for that variable.

A Concise Introduction To Prolog

Prolog generally prints yes when it has successfully completed a command, and no if it fails to. 3.3 Conjoining commands: Several commands can be typed one after another, provided commas are put between them (and a full stop after the last one). For example write('hello'), nl, write('master').

treating a single special case is already a usable Prolog program! If you have written out just one case of one predicate, you can immediately try it and simply add more code later. These features lead to early student success, and thus greatly enhance student confidence and motivation. Prolog programs define the behavior of predicates and

Prolog as the First Programming Language

A successful computation confirms that the conjunction in the initial query is a logical consequence of the program. EXAMPLE?- a, d, e. If this succeeds from a program P then the computed answer is a ∧ d ∧ e and we have P |= a ∧ d ∧ e Conversely: if the program P does not offer any successful
